Tornadoes

- types
- classification

Tornadoes

Tornado Classification

Scale	MPH	Expected Damage	Image
F-1	73-112	Moderate Damage	
F-2	113-157	Considerable Damage	
F-3	158-206	Severe Damage	
F-4	207-260	Devastating Damage	
F-5	261-318	Incredible Damage	

to be or not to be

Frequency by Class

Deaths by Class

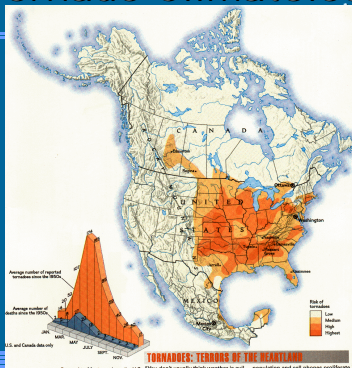

Classic Formation

Conditions for Big Storms

Tornado Climatology

Fronts and Weather

What a cold front does

The occluded front

Cold occlusion: Cold air behind, pushes air behind

Warm occlusion: Warm air behind, front rises up

A typical warm front

The Supercell

Other Severe Weather Features

Derechos

Watching out for 'bow echoes'

Trouble brewing
If a line of thunderstorms develops a bow shape, on radar, meteorologists know to watch it closely.

Watching out for 'bow echoes'

Bowing storms
Strong winds aloft push some storms in line forward rapidly. Rain, hail drags the winds to the ground.

Watching out for 'bow echoes'

Destructive Winds
Rain, hail drags the winds to the ground where they hit at speeds above 100 mph.

Gustfronts

A thunderstorm's long reach

The blast
Falling rain drags down cool air that spreads out as it slices the ground.

A thunderstorm's long reach

Gust fronts
Leading edge of the cool air forms a bulwaving, miniature cold front.

A thunderstorm's long reach

New storms
Advancing cool air pushes up warm, humid air, triggering new thunderstorms.

Prefrontal Squalls

Squall lines often destructive

Storms in a row
Advancing cold air gives thunder its upward, forming numerous thunderstorms in a long, narrow line.

Squall lines often destructive

Damaging winds
Falling air, snow evaporates, cooling the air. Cool, heavy air plunges, blasting the ground with high winds.

Microbursts

Microbursts & Airplanes

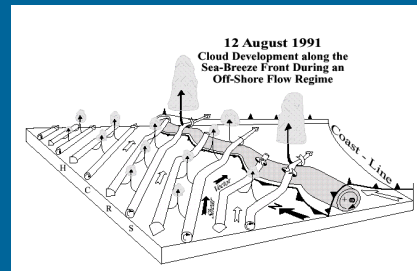

The Small Storms

Non-Supercell
Tornadoes

Small Storms

Forecasting
• current practice

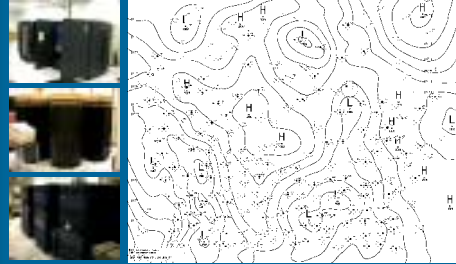

Upper Air Network

Current Upper Air Observational Network:
 • 110000 data for meteorological variables
 • 20000 data for upper air observations
 • 10000 data for surface observations
 • 10000 data for other variables

Surface Network

Numerical Weather Prediction

Satellite Cloud Detection

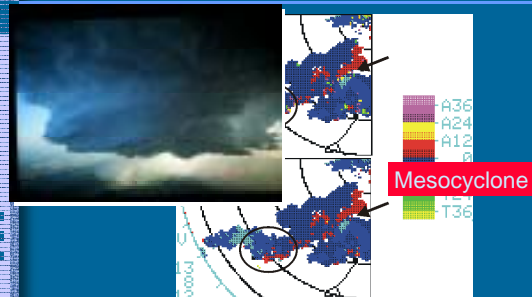

National Radar Project

The Forecaster

Severe Weather Signature

Warning Types

Type	Description
<i>Wind</i>	Strong winds that cause mobility problems and possible damage to vegetation and structures.
<i>Heavy Rainfall</i>	Heavy or prolonged rainfall accumulating on a scale sufficient to cause local/widespread flooding.
<i>Thunderstorm</i>	One or more of the following: strong winds causing mobility difficulty, damage to structures due to wind and hail, heavy rain that may cause local flooding and lightning.
<i>Severe Weather</i>	Presence of tornado(s), damaging hail, heavy rain, strong winds, life and property exposed to real threat, lightning
<i>Tornado</i>	Public has real potential to be exposed to tornado(s).

Some Recent Canadian Tornadoes

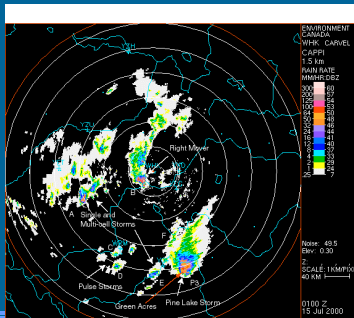

Pine Lake

Doppler Signature

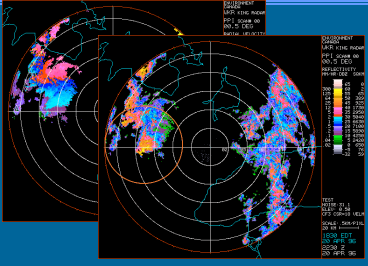

Which storm is severe?

Guelph Tornado

Williams Lake

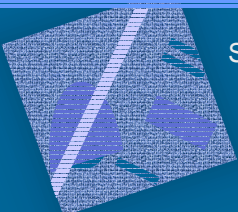

Mesocyclone Detection
Apr 20 1996 Williams Lake Tornado

What's Happening on the Ground?

The Future

Sydney 2000

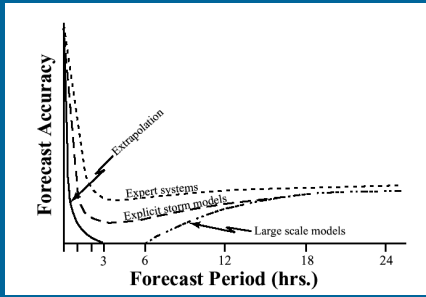

Sydney 2000

- Algorithmic Severe Weather diagnosis of the atmosphere
- Nowcasting (0+) of convective initiation and precipitation
- Combined to form the World Weather Research Program Sydney 2000 Forecast Demonstration Project

Demonstrate precision forecasting in time and space.

Forecast Ability

The graph plots Forecast Accuracy on the y-axis against Forecast Period (hrs.) on the x-axis (0, 3, 6, 12, 18, 24). Four curves are shown: 'Extrapolation' (steepest decline), 'Expert systems' (moderate decline), 'Explicit storm models' (shallow decline), and 'Large scale models' (shallowest decline).

Nowcasting

- **Observation** based short-term forecasting
- 0 to 6/12/24 hours
- 0 hours mean knowing what is happening now
 - diagnosis (eg of severe weather)
- 0+ hours mean predicting what is happening in the future
 - prognosis
 - extrapolation

The Players

Participant	System
UK Met Office	NIMROD - 6 hour nowcasts
UK Met Office	GANDOLF - 3 hour nowcasts
Canada MSC	CARDS - 90 minutes, Severe Weather
US NCAR	Autonowcaster - 90 minutes, forecast convection
US NSSL	WDSS - Severe Weather
Australia	SPROG - 90 minutes, Polarization Radar

Clients

Real time delivery of products to BOM forecasters and external clients to use in provision of weather services

Targeted Impact Studies for Nowcast Users

Nimrod 0 to 6 hrs Precip Nowcast

Successor to FRONTIERS (Forecasting Rain Optimised using New Techniques of Interactively Enhanced Radar and Satellite data) from 1997

Radar derived surface rain rate analysis

Nowcast scheme combines object-oriented rainfall advection with NWP mesoscale rainfall prediction

Inputs – synoptic observations, surface beam radar reflectivity, satellite, NWP mesoscale model outputs

Nowcasts from 0-6 hours, 15 min. time step, 5 km resolution

Products – instantaneous rain rate, 15 minute rain accumulation, precipitation type, wind gusts

Nowcasting methodology

Nimrod extrapolation and 'merged' forecasts

Extrapolation forecast 6 hours Use NWP to replace fill 10 hours

GANDOLF 0 to 3 hours Precip Nowcast

Designed to improve nowcasts of convective rain

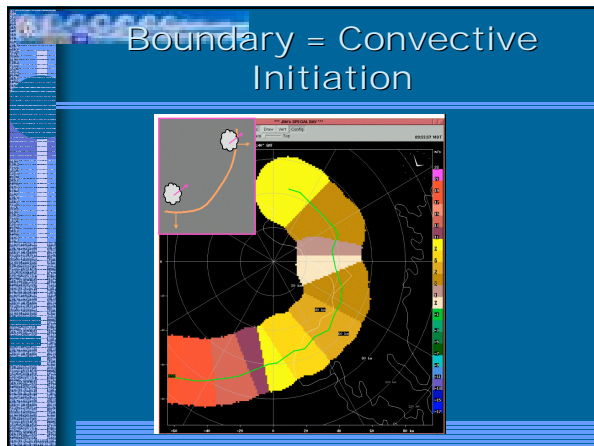

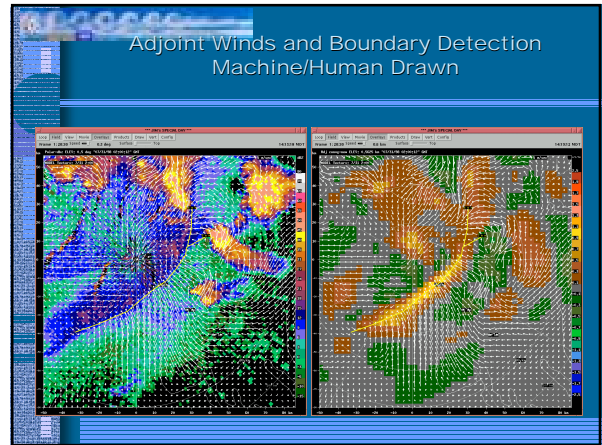

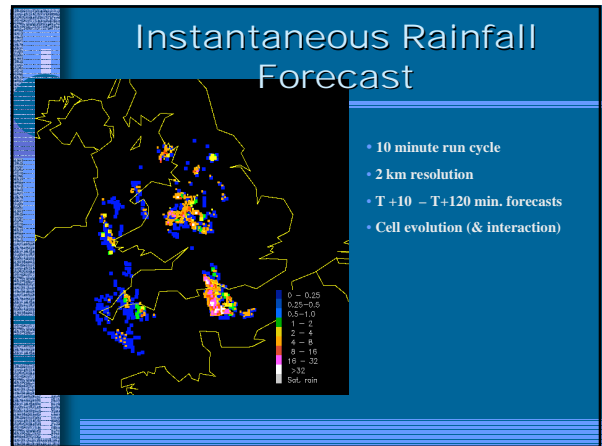

Radar derived 3-D rain analysis

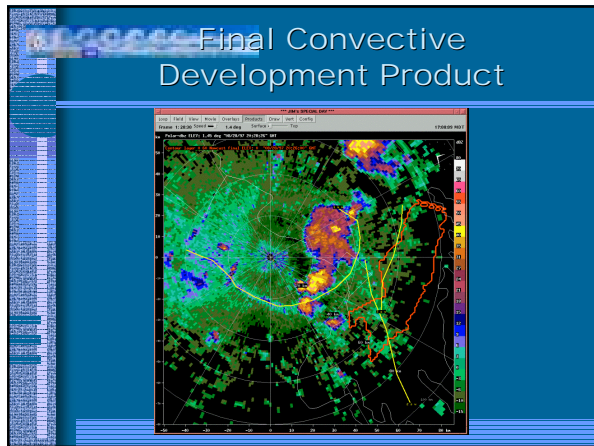

Object-oriented nowcast scheme with conceptual life cycle model of convective cell

Inputs – multi-beam / volumetric radar reflectivity, satellite, NWP mesoscale model outputs

Nowcasts from 0-2 hours, 10 min. time step, 2 km resolution

Products – instantaneous rain rate, 15 minute rain accumulation, storm / cell track, (hail diagnosis, peak convective wind gust)

Polarimetric Radar

September 2000
Hail detection with Polarization Radar

The Bureau of Meteorology's CPOL Polarimetric Doppler Research Radar now located temporarily at Badgery's Ck in support of the Sydney 2000 Project

Example of hail collected near Horsley Park NSW

National Severe Storms Laboratory Warning Decision Support System - Severe Weather Only

Table ranking the most severe storms

Detects storms and vortices and forecasts their movement.

Pop-up table alerting of rapidly growing storms

Time-height trend information from 130 million data points

One hour trend of storm parameters

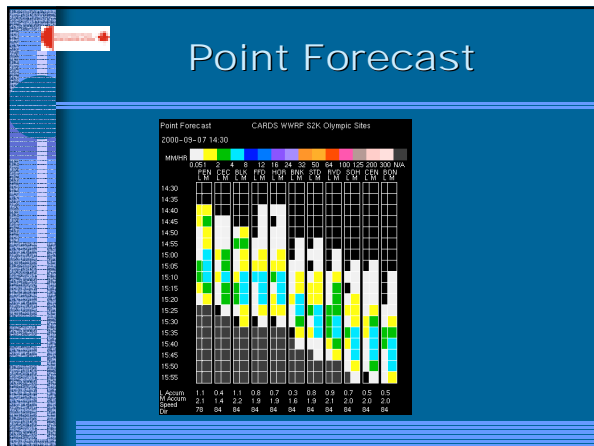

Probability of tornado and damaging winds from neural network

CARDS

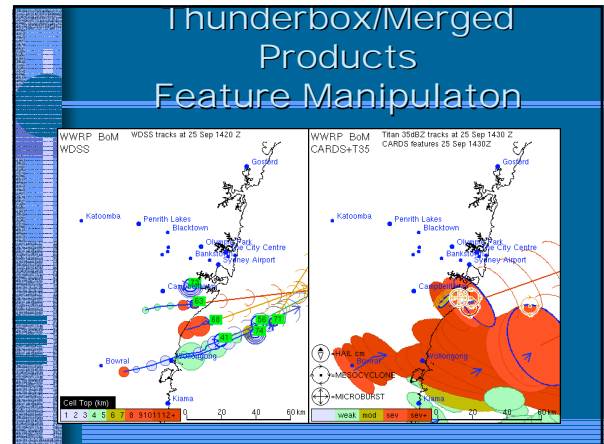

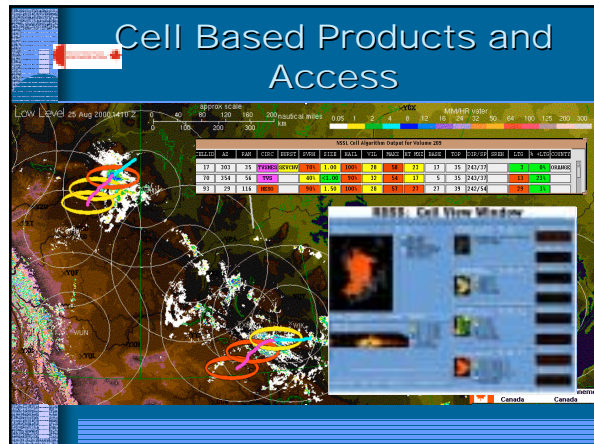

The Canadian Atmospheric Environment has developed a system to detect the severity of individual thunderstorms. Hail, downbursts, rotating storm updrafts and other severe weather signatures are detected automatically using Doppler radar data from the Bureau of Meteorology site at Kurnell.

Rings show locations of microbursts on 19 January 2000

Hail

Our Reality

- ## Summary
- Described the variety of Tornadoes
 - Described the current thinking about how they are formed
 - Described how severe weather forecasting is done
 - Described other tornado-like severe winds
 - Described where we are going in forecasting
